PSMA PEPTIDES vs ANTIBODY

Peptides are attractive targeting molecules due to their small size and ease of manufacture

For PET imaging the rapid systemic clearance, tissue distribution and tumor penetrance favor small peptides vs. other targeting moieties

	Peptides	Monoclonal antibodies
Target Affinity	High	High
Selectivity	High	High
Molecular weight (kDa)	1-2	150
Tumor penetration	High	Low
Blood clearance	Fast	Slow
Liver accumulation	Low	High
Dose limiting organ	tbd	Bone marrow

COST-RECOVERY

- Provide evidence that the drug has a potential clinical **benefit**
- Demonstrate that the data to be obtained from the clinical trial would be **essential** to establishing that the drug is effective or safe for the purpose of obtaining initial approval
- **Demonstrate that the clinical trial could not be conducted without charging because the cost of the drug is extraordinary to the sponsor**

UNIQUE REGULATORY APPROACH - KEY POINTS

UCLA

- **Two separate** NDAs : UCSF NDA 212643 and UCLA NDA 212642
- **Same clinical and non-clinical information**
- **Site-specific CMC** modules (Chemistry Manufacturing and Controls)
- **Similar package insert**; different vial label
- **Waiving market exclusivity**
- 505(b)(2) NDA pathway
  - Data from literature, not conducted by the applicant
  - Nonclinical pharmacology and clinical dosimetry

^{68}Ga-PSMA-11 PET is FDA APPROVED at UCLA and UCSF

WHAT DOES IT MEAN NOW? - KEY POINTS

- UCSF and UCLA **only** distribute 68Ga-PSMA-11 within their institutions
- UCSF and UCLA are filing new HCPCS code request with **Medicare (currently not covered)**
- Open to 68Ga-PSMA-11 ANDA applications immediately (Abbreviated)
  - **No patent protection**
  - **Market exclusivity waived**
  - **Not required**: nonclinical and clinical studies
  - **Required**: site and product/process specific CMC information
    - Final product composition, formulation, specification and controls;
    - manufacturing process and controls etc.

REGULATORY LANDSCAPE
(DIAGNOSTIC PET DRUGS INDICATED FOR PROSTATE CANCER)

- FDA Approved
  - 2012 Choline C 11 Injection
    - For positron emission tomography (PET) imaging of patients with suspected prostate cancer recurrence and non-informative bone scintigraphy, computerized tomography (CT) or magnetic resonance imaging.
  - 2016 AXUMIN (fluciclovine F 18) injection
    - Indicated for positron emission tomography (PET) imaging in men with suspected prostate cancer recurrence based on elevated blood prostate specific antigen (PSA) levels following prior treatment.
  - 2020 Gallium Ga 68 PSMA-11 Injection
    - Indicated for positron emission tomography (PET) of prostate-specific membrane antigen (PSMA) positive lesions in men with prostate cancer:
      - with suspected metastasis who are candidates for initial definitive therapy.
      - with suspected recurrence based on elevated serum prostate-specific antigen (PSA) level.
- Submitted to FDA (information disclosed in public domain)
  - Lantheus NDA for PyL™ (^{18}F-DCFPyL): Submitted September 2020; PDUFA date May 28, 2021
  - Telix NDA for TLX591-CDx (Kit for the preparation of ^{68}Ga-PSMA-11): Submitted September 2020; Accepted for filing in November 2020.

^{68}Ga-PSMA-11 PET is FDA APPROVED at UCLA and UCSF

FDA Approves First PSMA-Targeted PET Imaging Drug for Men with Prostate Cancer

Share Tweet Linkedin Email Print

For Immediate Release: December 01, 2020

Español

Today, the U.S. Food and Drug Administration approved Gallium 68 PSMA-11 (Ga 68 PSMA-11) – the first drug for positron emission tomography (PET) imaging of prostate-specific membrane antigen (PSMA) positive lesions in men with prostate cancer.

Gallium Ga 68 PSMA-11 Injection, for intravenous use
Initial U.S. Approval: 2020

----------INDICATIONS AND USAGE----------

Ga 68 PSMA-11 Injection is a radioactive diagnostic agent indicated for positron emission tomography (PET) of prostate-specific membrane antigen (PSMA) positive lesions in men with prostate cancer:

- with suspected metastasis who are candidates for initial definitive therapy.
- with suspected recurrence based on elevated serum prostate-specific antigen (PSA) level. (1)

STUDY DESIGN

Primary Endpoint

positive predictive value (PPV) on a per-patient and per-region basis of 68Ga-PSMA-11 PET for detection of tumor location confirmed by histopathology

STATS

- **Estimated sample size needed: ≥107 patients with biopsy and/or surgery follow-up**
- **Hypothesis: PPV of 70%**

Fendler WP et al. *JAMA oncol*. 2019

STUDY DESIGN

Primary Endpoint

positive predictive value (PPV) on a per-patient and per-region basis of 68Ga-PSMA-11 PET for detection of tumor location confirmed by histopathology or "composite" reference standard (PSA, imaging).

STATS

- **Estimated sample size needed: ≥107 patients with biopsy and/or surgery follow-up**
- **Hypothesis: PPV of 70%**

Fendler WP et al. *JAMA oncol*. 2019

STUDY DESIGN

COMPOSITE ENDPOINT

- Histopathology
- PSA decrease after focal therapy without ADT
- Correlation with Other imaging modality

STUDY DESIGN – COMPOSITE ENDPOINT

All patients will be followed up 3-12 months with conventional imaging (dedicated CT, MRI and/or bone scan). Interpretation of follow-up imaging will be performed by local read. For lesions that are reported in the blinded reads but not reported in the local evaluation of follow-up imaging, the local readers will be informed of the location of the lesions and follow-up will be performed for these additional lesions. Preferably, the follow-up conventional imaging should be the same modality/modalities as the initial staging work-up to allow for reproducible and accurate comparisons.

^{68}Ga-PSMA-11 PET validation based on follow-up imaging:

i) Lymph nodes will be assessed by change in size. ^{68}Ga-PSMA-11 positive lymph nodes will be considered:

(1) True positive:

- For patients undergoing systemic treatment (alone or in combination with targeted treatment): If on post-treatment follow-up imaging within 3-12 months, lymph nodes seen on CT or MRI decrease by more than 30% in short axis diameter and PSA declines by more than 50%.

  - If PSA increases by more than 50% on systemic therapy, then a increase in the size of lesion by more than 20% will be considered a true positive lesion.

- In subjects with localized suspected lymph node(s) receiving targeted treatment without concomitant systemic treatment there are two ways to meet true positive disease:

  - If the subject shows a decrease of PSA by greater than 50% after targeted treatment and the lymph node does not enlarge (change in size less than 20% or less than 3 mm increase in short axis diameter) [*OR*]

  - If on post-treatment follow-up imaging within 3-12 months, lymph nodes seen on CT or MRI decrease by more than 30% in short axis diameter (with a minimum of 3 mm in change in size)

- For untreated patients: If on follow-up imaging within 3-12 months, lymph nodes seen on CT or MRI increase by more than 20% in short axis diameter (with a minimum of 3 mm in change in size).

(2) False positive:

- For patients undergoing systemic treatment (alone or in combination with targeted treatment): If on post-treatment follow-up imaging within 3-12 months, lymph nodes seen on CT or MRI increase by more than 20% in short axis diameter and PSA decreases by more than 50%.

- In subjects with localized suspected lymph node(s) receiving targeted treatment without concomitant systemic treatment there are two ways to meet false positive disease:

  - If the subject does not demonstrate a decrease of PSA by greater than 50% after targeted treatment [*OR*]

  - If on post-treatment follow-up imaging within 3-12 months, lymph nodes seen on CT or MRI increase by more than 20% in short axis diameter (with a minimum of 3 mm in change in size)

- For untreated patients: If on follow-up imaging within 3-12 months, lymph nodes seen on CT or MRI decrease by more than 30% in short axis diameter (with a minimum of 3 mm in change in size).

(3) If all regions in a patient/region do not meet criteria for either True positive or False positive disease, then the patient/region will be considered inevaluable for primary endpoint.

ii) Visceral lesions (non-lymph node soft tissue or organ) will be assessed by change in size. ^{68}Ga-PSMA-11 positive visceral lesions will be considered:

(1) True positive:

- For patients undergoing systemic treatment (alone or in combination with targeted treatment): If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI decrease by more than 30% in long axis diameter and PSA declines by more than 50%.

  - If PSA increases by more than 50% on systemic therapy, then a increase in the size of lesion by more than 20% will be considered a true positive lesion.

- In subjects with localized suspected lesions(s) receiving targeted treatment without concomitant systemic treatment there are two ways to meet true positive disease:

  - If the subject demonstrates a decrease of PSA by greater than 50% after targeted treatment [*OR*]

  - If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI decrease by more than 30% in long axis diameter (with a minimum of 3 mm in change in size)

- For untreated patients: If on follow-up imaging within 3-12 months, lesions seen on CT or MRI increase by more than 20% in long axis diameter (with a minimum of 3 mm in change in size).

(2) False positive:

- For patients undergoing systemic treatment (alone or in combination with targeted treatment): If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI increase by more than 20% in long axis diameter and PSA decreases by more than 50%.

- In subjects with localized suspected lesions(s) receiving targeted treatment without concomitant systemic treatment there are two ways to meet false positive disease:

  - If the subject does not demonstrate a decrease of PSA by greater than 50% after targeted treatment [*OR*]

  - If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI increase by more than 20% in long axis diameter (with a minimum of 3 mm in change in size)

- For untreated patients: If on follow-up imaging within 3-12 months, lesions seen on CT or MRI decrease by more than 30% in long axis diameter (with a minimum of 3 mm in change in size).

(3) If all regions in a patient/region do not meet criteria for either True positive or False positive disease, then the patient/region will be considered inevaluable for primary endpoint.

iii) ^{68}Ga-PSMA-11 positive bone lesions will be considered:

(1) True positive:

- If there was a corresponding positive sclerotic lesion on the CT portion of the ^{68}Ga-PSMA-11 PET or on a separate CT obtained ≤ 30 days before or after the PET/CT in the same location as the PSMA uptake.

- If there is focal uptake seen in the same location as the PSMA uptake on the baseline bone scan performed within one month of ^{68}Ga-PSMA-11 PET.

- If there is a lesion noted in the same location as the PSMA uptake on the initial MRI performed within one month of ^{68}Ga-PSMA-11 PET.

- If within 12 months follow-up CT demonstrates development of sclerosis in the same location as the PSMA uptake.

- If within 12 months follow-up MRI demonstrates a new bone lesion in the same location as the PSMA uptake.

- If within 12 months follow-up bone scan demonstrates new focal uptake in the same location as the PSMA uptake.

- In subjects with localized suspected bone lesion(s) receiving targeted treatment without concomitant systemic treatment:

  - If the subject demonstrates a decrease of PSA by greater than 50% after targeted treatment.

(2) False positive:

- In subjects with localized suspected bone lesion(s) receiving targeted treatment without concomitant systemic treatment:

  - If the subject does not demonstrate a decrease of PSA by greater than 50% after targeted treatment with curative intent (ie non-palliative radiation).

- If ^{68}Ga-PSMA-11 positive bone lesions do not meet the criteria for true positive findings, and appropriate correlative and follow-up imaging was acquired.

STUDY DESIGN – COMPOSITE ENDPOINT

(3) If bone lesions do not meet criteria for either true positive or false positive disease listed above, then the patient/region will be considered inevaluable for primary endpoint.

iv) ^{68}Ga-PSMA-11 positive prostate bed and prostate lesions will be considered:

(1) True positive:

- For patients undergoing systemic treatment (alone or in combination with targeted treatment): If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI decrease by more than 30% in long axis diameter

- In subjects with localized suspected lesions(s) receiving targeted treatment without concomitant systemic treatment there are two ways to meet true positive disease:

  - If the subject demonstrates a decrease of PSA by greater than 50% after targeted treatment [*OR*]
  - If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI decrease by more than 30% in long axis diameter (with a minimum of 3 mm in change in size)

- For untreated patients: If on follow-up imaging within 3-12 months, lesions seen on CT or MRI increase by more than 20% in long axis diameter (with a minimum of 3 mm in change in size).

(2) False positive:

- For patients undergoing systemic treatment (alone or in combination with targeted treatment): If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI increase by more than 20% in long axis diameter and PSA decreases by more than 50%.

- In subjects with localized suspected lesions(s) receiving targeted treatment without concomitant systemic treatment there are two ways to meet false positive disease:

  - If the subject does not demonstrate a decrease of PSA by greater than 50% after targeted treatment [*OR*]
  - If on post-treatment follow-up imaging within 3-12 months, lesions seen on CT or MRI increase by more than 20% in long axis diameter (with a minimum of 3 mm in change in size)

- For untreated patients: If on follow-up imaging within 3-12 months, lesions seen on CT or MRI decrease by more than 30% in long axis diameter (with a minimum of 3 mm in change in size).

(3) If the lesion does not meet criteria for either True positive or False positive disease, then the lesion will be considered inevaluable for primary endpoint.

c) Histopathology/Biopsy:

i) ^{68}Ga-PSMA-11 positive findings are aimed to be confirmed by histopathology/biopsy if clinically feasible. Pathology performed 60 days before the PSMA PET will be available for correlation.

ii) Histopathological procedures and biopsies will be performed as clinically indicated and as per institutional protocol.

(1) Positive Histopathology/Biopsy: Confirmed sites of metastatic or tumor involvement by histopathology/biopsy will be discussed with the responsible physician/surgeon.

(a) True Positive: lesion is positive on targeted biopsy/surgical sampling and is read as positive on PSMA PET.

(b) False Negative: lesion is positive on targeted biopsy/surgical sampling and is read as negative on PSMA PET.

(2) Negative Biopsy: Patients with suspected tumor recurrence on ^{68}Ga-PSMA-11 PET with negative histopathology/biopsy will be handled as outlined below:

(a) Lymph nodes:

- For patients undergoing nodal dissection: Patients will be rescanned with dedicated CT, MRI or a repeat ^{68}Ga-PSMA-11 PET to determine if the suspicious ^{68}Ga-PSMA-11 positive node was removed.

  1. If ^{68}Ga-PSMA-11 positive lymph node is still present, a repeat biopsy can be pursued if clinically feasible and applicable, or follow-up using imaging as described above will be performed.
  2. If the corresponding node was removed, then this will be considered a False Positive.

- For patients undergoing needle biopsy: Images of the procedure will be reviewed to determine if the correct node was biopsied.

  1. If the correct node was biopsied, then a negative biopsy will be considered a False Positive.
  2. If the incorrect node was biopsied, then follow-up imaging as described above will be performed.

(b) Bone lesions: Given the high rate of false negative biopsies for osseous metastases in patients with prostate cancer, patients with negative bone biopsies of PSMA PET positive lesions will be further evaluated:

- If pathology demonstrates an alternative diagnoses that is known to be PSMA positive (eg Renal Cell Carcinoma metastases, Paget's disease), then this will be considered a False Positive.
- If pathology is indeterminate, then follow-up imaging as described above will be performed.

(3) Although not routinely performed during standard practice, immunohistochemical staining for PSMA of tumor specimens (primary and lymph node metastases) may be performed, although not required.

d) Definitions of True Positive, False Positive, True Negative, and False Negative patients and regions: Pathology will be considered superior to imaging and clinical follow-up when available as described below. Patient and region level classification will be performed for each blinded reader, and be reported separately. The following criteria serve as a guide for interpretation. However not all findings on a lesions, region and patient level can be detailed here and investigators may deviate from these criteria in individual patients. These will be recorded for each interpretation that is not described in this protocol for the definition of a region or patient.

i) Patient level evaluation:

(1) True positive patient: A single region in a patient contains a true positive node either by pathology or imaging/clinical follow-up.

(a) For a patient to be considered a True Positive, only one region is required to have a true positive lesion as described above, unless one region is categorized as a false positive based on pathology. This means that a single pathology false positive region outweighs regions with imaging/clinical follow-up true positive disease.

(b) A patient will be considered a True Positive if one region contains a lesion that is True Positive, even if other regions are categorized as inevaluable or false positive based on imaging or clinical follow-up.

(2) True negative patient: in the absence of True Positive or False Positive lesions, a patient will be considered a True Negative if there is pathology that is negative for disease and corresponding lesion is negative by PSMA PET.

(3) False positive patient:

(a) Pathology confirms a false positive lesion that is read as positive on PSMA PET.

(b) In the absence of pathology: there are no true positive regions, and there is a region that is categorized as false positive based on imaging or clinical follow-up.

(4) False negative patient: in the absence of True Positive or False Positive lesions, a patient will be considered a False Negative if there is pathology that is positive for disease and corresponding lesion is negative by PSMA PET.

ii) Region level evaluation: Each patient will have four evaluable regions (Table 1: prostate bed, pelvis, extrapelvic soft tissue, and bone metastases). Each region will be categorized as true positive or false positive as described above. Regions without evidence of PSMA positive disease or deemed inevaluable will not be included in the analysis.

(1) True positive region:

(a) Pathology confirms a PSMA avid lesion as a true positive in the region.

STUDY DESIGN

Primary Endpoint

positive predictive value (PPV) on a per-patient and per-region basis of 68Ga-PSMA-11 PET for detection of tumor location confirmed by histopathology or "composite" reference standard (PSA, imaging).

STATS

- **Estimated sample size needed: ≥107 patients with biopsy and/or surgery follow-up**
- **Hypothesis: PPV of 70%**

3 blinded independent central readers (BICR) with no clinical data available (**Majority Score 2:1**)

STUDY PROTOCOL Open Access

Randomized prospective phase III trial of ^{68}Ga-PSMA-11 PET/CT molecular imaging for prostate cancer salvage radiotherapy planning [PSMA-SRT]

Jeremie Calais[1*], Johannes Czernin[1*], Wolfgang P. Fendler[1,2], David Elashoff[3] and Nicholas Nicholas G. Nickols[4,5]

Abstract

Background: Salvage radiotherapy (SRT) for prostate cancer (PCa) recurrence after prostatectomy offers long-term biochemical control in about 50–60% of patients. SRT is commonly initiated in patients with serum PSA levels < 1 ng/mL, a threshold at which standard-of-care imaging is insensitive for detecting recurrence. As such, SRT target volumes are usually drawn in the absence of radiographically visible disease. ^{68}Ga-PSMA-11 (PSMA) PET/CT molecular imaging is highly sensitive and may offer anatomic localization of PCa biochemical recurrence. However, it is unclear if incorporation of PSMA PET/CT imaging into the planning of SRT could improve its likelihood of success. The purpose of this trial is to evaluate the success rate of SRT for recurrence of PCa after prostatectomy with and without planning based on PSMA PET/CT.

Methods: We will randomize 193 patients to proceed with standard SRT (control arm 1, $n = 90$) or undergo a PSMA PET/CT scan (free of charge for patients) prior to SRT planning (investigational arm 2, $n = 103$). The primary endpoint is the success rate of SRT measured as biochemical progression-free survival (BPFS) after initiation of SRT. Biochemical progression is defined by PSA ≥ 0.2 ng/mL and rising. The randomization ratio of 1:1.13 is based on the assumption that approximately 13% of subjects randomized to Arm 2 will not be treated with SRT because of PSMA-positive extra-pelvic metastases. These patients will not be included in the primary endpoint analysis but will still be followed. The choice of treating the prostate bed alone vs prostate bed and pelvic lymph nodes, with or without androgen deprivation therapy (ADT), is selected by the treating radiation oncologist. The radiation oncologist may change the radiation plan depending on the findings of the PSMA PET/CT scan. Any other imaging is allowed for SRT planning in both arms if done per routine care. Patients will be followed until either one of the following conditions occur: 5 years after the date of initiation of randomization, biochemical progression, diagnosis of metastatic disease, initiation of any additional salvage therapy, death.

Discussion: This is the first randomized phase 3 prospective trial designed to determine whether PSMA PET/CT molecular imaging can improve outcomes in patients with PCa early BCR following radical prostatectomy.

Acronym: PSMA-SRT Phase 3 trial.
